Introduction

A query is a tool for extracting, combining, and displaying data from one or more tables, according to criteria you specify. For example, in a book inventory database, you could create a query to view a list of all hardcover books with more than 500 pages that you purchased in the past five months. In a query, you can sort information, summarize data (display totals, averages, counts, and so on), display the results of calculations on data, and choose exactly which fields are shown. You can view the results of a query in a tabular format, or you can view the query’s data through a form or on a report (which is covered in Plug-In T8, “Decision Making Using Access 2013”). In this plug-in, you will learn how to use the Query Wizard and Query-By-Example (QBE) tool to solve problems using Microsoft Access.

Creating Simple Queries

Use the Query Wizard to create a select query. A select query displays data from a table or tables, based on the fields that you select, but it does not sort or filter the data. For example, if you owned a bicycle shop and wanted a list of customer names that rented bikes, you could use a simple query that would show fields from a CUSTOMER table.

To create a query using the Simple Query Wizard:

1. Open the file T7_SlopesideBikes_Data.mdb from the data file that accompanies this text.
2. You will see a Security Warning. Click on the Options button and select Enable this content. Click OK.
3. Click the **Create** tab and then click the **Query Wizard** button.
4. In the **New Query** dialog box, select **Simple Query Wizard** and then click **OK**.
5. Once the wizard opens, click the **Tables/Queries** drop-down arrow. Select **Table: CUSTOMER** (refer to Figure T7.1).
6. Add all the fields by clicking on the **right double arrow (>>) button**.
7. Click **Next**.
8. In the next window, make sure the radio button **Detail** is selected and click **Next**.
9. In the next window, type **Customer Query** as the Query title and select the radio button for **Open the query to view information**.
10. Click **Finish** to view the query in **Datasheet** view (refer to Figure T7.2).
11. Close the query (it will automatically be saved).

By modifying the query in Design view, you can specify that the query display only records that meet certain criteria or that the query display records in a specific order.

**Note:** Keep in mind that a query database object stores only the query definition—field names, data selection criteria, sorting orders, grouping information, and so on. It does not store the actual data that it displays; that data is stored only in the database tables. Consequently, every time you run a particular query, it shows the current state of the data stored in the database tables.

### REORDERING COLUMNS IN THE SELECT QUERY DATASHEET

If you use the Query Wizard, the query datasheet displays fields in the order you added them. You can reorder columns by clicking and dragging.

To reorder columns (refer to Figure T7.3):

1. Open the **CUSTOMER Query** by double-clicking on it in the **Navigation Pane**.
2. Click the **First Name** field selector and then click it again and drag it to the left one column (i.e., **First Name** should now be to the left of **Last Name**).
3. Notice the dark, thick column border line that appears to the left of the selected column. As you move your mouse across the screen, the column border line will move with it.

4. Close and save the query.

Note: You can select adjacent columns by clicking a field selector and dragging the mouse across other field selectors, then clicking one of them again to drag the whole selection.

CREATING A SELECT QUERY IN DESIGN VIEW

You do not have to use the Query Wizard to create select queries; you can create a new select query in Design view (which can be referred to as a Query-By-Example, or QBE, tool).

To create a select query in Design view (refer to Figure T7.4):

1. Click the Create tab and then click the Query Design button in the Other group.
2. Click the name of the BIKE table. Click the Add button.
3. Click the Close button to continue.
4. Double-click the Bike ID field in the field list at the top of the query window. You can also click the name and drag it to the query design grid below.

5. Double-click the Description field in the field list.

6. Run the query by clicking the Run button in the Results group (see Figure T7.5).

7. Close and save the query as Bike List.

    **Note:** If you want to include all the fields from a table in your query, click and drag the asterisk (*) to the field row in the query design grid. Notice that rather than listing each field from the table separately, there is only one field called table. The * character represents a wild card. Rather than look for specific field names, the query will look for all the fields in that table. Therefore, if you later add or delete fields, you will not need to change the query design.

    You can add tables to the field list by clicking the toolbar button or selecting Show Table from the Query Setup group of the Design tab menu.

**ADDING SELECTION CRITERIA TO A SELECT QUERY**

Although a select query displays only the fields you select, by default, it will show all of the records. By modifying the select query in Design view, you can refine the query so that it shows only records that meet specific criteria. You can also hide fields so they do not display in Datasheet view.

To specify criteria for a select query:

1. In the Navigation Pane, click the Bike List query, right-click and click on Design View.

2. In Design view, double-click the Cost Per Hour field under BIKE in the field list.

3. Click in the Criteria cell under the Cost Per Hour field and type in <15 (refer to Figure T7.6).

4. Run the query.

5. Close and save the query as Bikes Under $15.
If you need to hide a query field in **Datasheet** view:

1. **In Design** view, click in the **Show** check box, in the query design grid, to remove the checkmark for the field you want to hide.
2. Run the query.

   **Note:** Criteria expressions are not case-sensitive.

**SORTING DATA IN A SELECT QUERY**

You can control how records in a query appear in Datasheet view by using the sort feature.

To modify the select query to sort records:

1. Open the **Bikes Under $15** query that you created in the previous section.
2. **In Design** view, click **Sort** under the **Description** field.
3. Click the drop-down arrow and select the **Ascending** button (**Sort Smallest to Largest**).
4. Run the query.
5. Close and save the query as **Sorted Bikes Under $15**.

   If you want to sort the results of a select query while in Datasheet view:

1. Click in the field that you want to sort on.
2. **Click the Sort Ascending or Sort Descending toolbar button in the Sort & Filter group on the ribbon.**

   **Note:** If two fields have the sort option selected, Access will sort by the farthest left field first.
Advanced Queries

Database fields generally display the data that are entered into them. However, a calculated field will automatically figure its value based on values in other fields. Queries often include calculated fields that display values based on other values returned by the query.

To enter formulas in calculated fields, follow these steps:

1. Click the Create tab and then click the Query Design button.
2. Click the names of the BIKE, CUSTOMER, and RENTAL tables in the Navigation Pane (hold down the CTRL key to select each one). In the Show Table dialog box that appears, click the Add button.
3. Click the Close button to continue.
4. Double-click the Last Name and First Name fields from the CUSTOMER table, double-click the Date field from the RENTAL table, and double-click the Description field from the BIKE table.
5. To add a new calculated field, click inside the field row of a blank column, and type Rental Amount:—this is the name of an anonymous field (it is actually a variable name to hold the value of the calculated field).
6. Now you will enter the expression to be calculated. Type in: \((\text{[Time In]}-\text{[Time Out]})\times24\times\text{[Cost Per Hour]}\) (refer to Figure T7.7). **Note:** When referring to a field name, enclose the name in brackets. You can use standard mathematical operator symbols like \* (multiplication), /. (division), + (addition), − (subtraction), and \^ (exponentiation).
7. Click on the Show check box under the Rental Amount column.
8. Run the query (click Run button in toolbar) to see the results of the calculated field.
9. Close and save the query as Rental Amount.

**FIGURE T7.7**
Expression to Be Calculated

Enter expression to be calculated.
Note: When using a calculated field to combine text fields, you usually want to hide the text fields that are being combined and show only the new calculated field.

USING THE EXPRESSION BUILDER

You do not always have to type your calculated field expressions. The Expression Builder lets you construct expressions with just a few clicks of the mouse. It even has a built-in checker, so you will know right away if you have made a mistake.

To create a calculated field with the Expression Builder:

1. Click the Create tab and then click the Query Design button.
2. Click the names of the BIKE, CUSTOMER, and RENTAL tables in the Navigation Pane (hold down the CTRL key to select each one). Click the Add button.
3. Click the Close button to continue.
4. Double-click the Last Name and First Name fields from the CUSTOMER table, double-click the Date field from the RENTAL table, and double-click the Description field from the BIKE table.
5. Position the insertion point in the field row of the next blank column in the query design grid. Click the Builder toolbar button, found in the Query Setup group.
6. In the Expression Builder dialog box (see Figure T7.8), click the () button, and then double-click the Tables folder in the lower left pane.
7. Double-click the Rental subfolder. In the middle pane, double-click on Time In, click on the – button, double-click on Time Out, then double-click the ) button.
8. Continue to build the expression in the Expression Builder dialog box.
9. Click OK to add the expression to your query.
10. Run the query to see the results of the calculated field.
11. Close and save the query as Rental Amount 2.

When you create a new calculated field, by default, Access will set the Show option in the query design grid to off. Be sure to check the Show check box, or your new field will not show when you run the query.

When you create a calculated field with the Expression Builder, Access will automatically name the field Expr1. Rename the field by clicking in the field name box and typing the name you want before the colon that precedes the expression. Be sure not to delete the colon after the name; Access needs it to know that this is a calculated field.

USING AGGREGATE FUNCTIONS TO CALCULATE TOTALS IN QUERIES

Access includes a group of powerful built-in commands known as aggregate (or total) functions. Using aggregate functions, you can easily calculate totals for groups of records returned by the query specifications. Aggregate functions can calculate the sum, minimum, maximum, average, count, variance, and standard deviation. In the Query Design window, you should include a field to group by as well as the field that contains the values needed for the calculation. The values of aggregate calculations are not stored in the table; instead, Access recalculates the totals each time the query is run.
To use aggregate functions in queries:

1. Click the **Create** tab and then click the **Query Design** button.
2. Click the name of the **BIKE** table and click the **Add** button.
3. Click the **Close** button to continue.
4. Double-click the **Description** and **Cost Per Hour** fields.
5. Click the **Totals** button (the Sigma icon on the menu bar in the **Show/Hide** group) to add the **Total** row to the query design grid (refer to Figure T7.9).
6. Click in the **Total** row for the **Description** field. Click the drop-down arrow and select the **Group By** function.
7. Click in the **Total** row for the **Cost Per Hour** cell. Click the arrow and select the **Avg** function (refer to Figure T7.9).
8. Click the **Run** button on the toolbar.
9. Notice that the query does not return individual records. Instead, there is one row for each unique value in the **Group By** field. Each row shows the calculated total for that group of records (refer to Figure T7.10).
10. Close and save the query as **Bike Average Cost Per Hour**.

**Note:** Queries with aggregate calculations are often used to form the basis for strategic analysis or statistical reports.

**FORMATTING RESULTS DISPLAYED IN A CALCULATED FIELD**

You can specify the format for calculated field results by changing the **format property**.

To use the format property for calculated fields:

1. Open the **Rental Amount** query in **Design** view.
2. Right-click in the **Rental Amount** calculated field.
3. Click Properties . . . from the shortcut menu.
4. Click in the Format box.
5. Click the drop-down arrow.
6. Scroll down and click the Currency format.
7. Close the Field Properties dialog box by clicking the close box in the upper right corner.
8. Click the Run button.
9. Close and save the query.

**Note:** Be careful that you are viewing the field properties and not the query properties. If the field does not have the Show check box checked, you will open the Query Properties dialog box instead of the Field Properties dialog box.

**CREATING AND RUNNING QUERIES TO MODIFY DATA**

So far, this plug-in has described one major type of query: the select query. Four additional types of queries, which are known as *action queries*, can actually change your data:

1. A Make Table query.
2. An Append query.
3. A Delete query.
4. An Update query.

To use action queries:

1. Create a new query in Design view as you’ve done previously.
2. Select the BIKE table and click Add in the Show Table dialog box that appears.
3. Click Close to continue.
4. Double-click the Cost Per Hour field to add it to the query grid.
5. Convert the query to an action query by choosing the Update button in the Query Type group on the toolbar (refer to Figure T7.11).
6. Notice that you now have another line—Update To:—on the query design grid.
7. Click inside the **Update To: row** and type in \( \text{[Cost Per Hour]} + .50 \) (this will add 50 cents to each cost per hour).

8. Run the query. You will first get a warning message, like that shown in Figure T7.12. Click **Yes**.

9. Close and save the query as **Update Query**.

   **Note:** Make Table, Append, and Delete queries work the same way as the Update Query example above. Before running any of the queries, make a backup copy of your database. These queries can permanently modify your database, possibly removing a large amount of data.
**PLUG-IN SUMMARY**

A query is a tool for extracting, combining, and displaying data from one or more tables, according to criteria you specify. You can use the Query Wizard or Query-By-Example tool to select specific data from a table or tables. You can sort the rows of a query by a particular field, hide a particular field, enter a value to search on, summarize information, and even modify data using a query.

**MAKING BUSINESS DECISIONS**

1. **ProSwing Analysis**

   Carol Redden had been a part-time tennis instructor for several years. Frustrated with the tennis equipment available in the market, she started her own company. With the aid of her attorneys and investors, she founded ProSwing to design tennis equipment and apparel.

   Carol developed a strong product line and was becoming successful in the United States, but she was having trouble with the firm’s international marketing strategy. Carol thought that the most effective way to advertise was by getting players to use and wear her products. She wanted to be sure that the players using her line were the players followed by the fans (her target market). She knew that this would bring ProSwing attention from tennis players around the world. She decided to concentrate on the tennis players with the highest current winnings, since they were likely to be very popular and visible to the fans. She would approach the top 25 international men and women players about using ProSwing products. She would then additionally advertise during tennis matches in the four countries most represented by the top players in order to represent both the men and women top players.

   Carol prepared a database after finding recent sport statistics on the Web and compiled data on the top players. Included in the database are the player’s name, country of residence, most recent winnings, and gender. Carol needs your help to organize the data to plan her international strategy. She has provided you with the database file T7_ProSwing_Data.mdb in order to complete the following:

   1. Create a query that will sort the player data in descending order by winnings. Save the query as **Player Winnings Query**.
   2. Create a query that will sort the data in ascending order by Country Name and then in descending order by Winnings within each country. Change the order of the columns so that Country is the first column, followed by Winnings, and then Player. Save the query as **Country Winnings Query**.
   3. Create a query that will total the winnings for each country. Use the Country Name for the criteria and sort the Winnings in descending order. Save the query as **Total Winnings for Country Query**.

2. **WasteNot Recycling**

   WasteNot Recycling is an organization that picks up recyclables from homeowners in Boulder, Colorado, as introduced in Plug-In T6. The CUSTOMER table holds static customer information such as name, address, and phone. The CUSTOMER RECORD table holds data
about each recyclable pickup. Enough test data has been added to each table to test queries (use the \textit{T7\_WasteNotRecycling\_Data.mdb} file associated with this text).

The owners of WasteNot Recycling have asked you to assist with creating several queries. Specifically they need you to do the following:

1. Create a query using the CUSTOMER data that will select records for customers who had their first pickup in May 2004. Sort the records by customer’s Last Name. Save the query as \textit{May Pickup Query}.
2. Create a query on CUSTOMER RECORD to determine the total weights of paper and other products each customer has had picked up. Use the CUSTOMER Last Name and First Name in the query. Save the query as \textit{Customer Weight Query}.
3. Create a query using the Name, Street, Address, and Weight fields from the CUSTOMER DETAIL table. Enter the criteria that will select customers with less than 10 pounds in either recyclable field. Save the query as \textit{Low Volume Query}.

3. Scale Classic Cars
Johnny Krol runs a body shop that specializes in restoring classic cars. Johnny owns three classics and began collecting scale models when his wife put her foot down and said no to building more garage space for his cars.

Although Johnny frequently used the Internet and e-mail, he had never considered starting an e-business. The Scale Classics Web site began as a technology class project for Johnny’s son J.J., who created a basic text and graphics informational site. Johnny liked the site, but wanted a complex site dedicated to the serious collector. He envisioned a storefront, auction house, and collector’s forums and had been unable to find such a site in his online searches. Johnny hired a local consultant to build the site, found a processing house to manage orders and payments, and began shipping scale models from the body shop.

The storefront is largely for American classic cars, which come in 1/18, 1/24, 1/43, and 1/64 scale. Popular foreign cars are also available. Johnny has hired you to create some business analysis queries; specifically he wants you to:

1. Use the \textit{T7\_ClassicCars\_Data.mdb} database.
2. Create a query to select any record with “coupe” in the model name. Include the Make and Model in the query. Save the query as \textit{Coupe Query}.
3. Create a query to select the models that cost less than $35. The query should display the Car ID, Make, Model, and Price fields and sort the result from the highest to the lowest price. Save the query as \textit{Less Than $35 Query}.
4. Create a query listing classic cars grouped by their make. The query should display only the Make, Model, and Price fields. Sort by the model and calculate the average price for each make. Save the query as \textit{Cars By Model Query}.

4. BookFinder.com
BookFinder.com is an open marketplace for books online, a one-stop e-commerce search engine where you can search through more than 100 million new, used, rare, and out-of-print books for sale.

The site is produced by a team of high-tech librarians and programmers, working since 2004 to connect readers with the books they are looking for. They are part of their own audience; members of the BookFinder.com team are heavy readers and buy several dozen books every year using BookFinder.com. They also blog about their work, connecting readers and booksellers from around the world and supporting public access to a strong, diverse bookselling industry.
BookFinder.com was first developed in 2004 by then-19-year-old University of Denver undergraduate Charles Cook (as a personal Web site). Over the years, the site has grown to become one of the best online resources for book-related e-commerce, as evidenced by the great feedback received from users and the press. Whether customers collect rare books or buy cheap paperbacks to read, BookFinder.com is an unbiased marketplace and search engine.

Charles needs help developing some custom queries for his sales and marketing team members. He has provided you with a sample data file, T7_BkFinder_Data.mdb. Specifically, what Charles needs is:

1. A query of all authors who have written a book that costs more than $10 and is a novel. The query needs to have the author’s First Name, Last Name, Title of Book, Price, and Category displayed. Save the query as **Authors Query**.

2. A query that calculates a 15 percent increase in the purchase price of each book. Format the calculated field with the Currency format. Sort the query on the new calculated field. Save the query as **Book Prices Query**.

3. A query that displays the minimum price of all the books. Save the query as **Min Book Price Query**.

4. A query that updates the price of each book by subtracting 50 cents. Save the query as **Less 50 Cents Query**.
